Coding Challenge - Abalone

In Grover we are working on streaming data processing. In this task we would like you to write a streaming application in a language of choice (preferably Rust or Python). The data file abalone_full.csv contains marine gastropod called Abalone's features.

Please solve the challenge below by meeting the given acceptance criteria. When you have finished please ZIP your solution and do not publish your solution in any public GitHub repository or anywhere else!

In general, feel free to make assumptions and have fun with the challenge! Please make sure you focus your time on explaining and elaborating your thought process, assumptions, decisions, thoughts and comments, for example inside a thought-process.md file. Please also document how to build and run your code.

Data features

Acceptance Criteria

- We want to have streaming application which will produce CSV files according to these rules:
 - infants_with_more_than_14_rings.csv which will have all infants who have 14 or more rings. For all infants exactly the same number of rings, we want to enumerate and give an id to them. Final CSV will contain also id column.
 - males_heavy_and_short.csv which will have all the males with Whole_weight more than 0.4 and Length is less than 0.5. Please consider adjustable values for these constraints in your design. Like in the previous task since there is no count needed, you can enumerate all elements with incrementing id field.
 - Optional: shell_humidity.csv will contain (Whole_weight Shucked_weight) Shell_weight for every abalone to get the idea of how much water is absorbed in the abalones' shell. This feature

will be added as a separate column called shell_humidity_weight. Data extracted to this column cannot be negative, and all rows which computes negative value should be omitted from the output csv. In addition to that, id field is useful to have in the output CSV file.

- Make three processing tasks above concurrent if possible.
- Output CSV files will contain all fields in the source data and id field.

Tech Stack

- Rust or Python (others also possible)
- No external databases, do all processing in memory to avoid complexity.
- Application should conform streaming mentality.
- Test code where you feel it makes sense
